CONCLUSIONES	
BIBLIOGRAFÍA	

INTRODUCCION

SQL es un lenguaje específico del dominio que da acceso a un sistema de gestión de bases de datos relacionales que permite especificar diversos tipos de operaciones en ellos. Una de sus características es el manejo del álgebra y el cálculo relacional que permiten efectuar consultas con el fin de recuperar, de forma sencilla, información de bases de datos, así como hacer cambios en ellas. SQL (Lenguaje estructurado de consulta) es un lenguaje específico de dominio que se usa en la programación y está diseñado para manejar los datos que hay en un sistema de base de datos, o para el procesamiento de flujos de datos en un sistema de gestión de flujos.

El lenguaje de definición de datos (en inglés *Data Definition Language*, o *DDL*), es el que se encarga de la modificación de la estructura de los objetos de la base de datos. Incluye órdenes para modificar, borrar o definir las tablas en las que se almacenan los datos de la base de datos. Existen 3 operaciones básicas: CREATE, ALTER y DROP.

CREATE

Este comando permite crear objetos de datos, como nuevas bases de datos, tablas, vistas y procedimientos almacenados.

Ejemplo (crear una tabla)

```
CREATE TABLE 'CUSTOMERS';
```

ALTER

Este comando permite modificar la estructura de una tabla u objeto. Se pueden agregar/quitar campos a una tabla, modificar el tipo de un campo, agregar/quitar índices a una tabla, modificar un trigger, etc.

Ejemplo (agregar columna a una tabla)

```
ALTER TABLE 'ALUMNOS' ADD EDAD INT UNSIGNED;
```

DROP

Este comando elimina un objeto de la base de datos. Puede ser una tabla, vista, índice, trigger, función, procedimiento o cualquier objeto que el motor de la base de datos soporte. Se puede combinar con la sentencia ALTER.

Ejemplo

```
DROP TABLE 'ALUMNOS';
```

SELECT

Esta sentencia nos permite consultar los datos almacenados en una tabla de la base de datos.

```
SELECT [ALL | DISTINCT ]
              <nombre campo> [{,<nombre campo>}]
FROM <nombre tabla>|<nombre vista>
        [{,<nombre tabla>|<nombre vista>}]
[WHERE <condición> [{ AND | OR <condición>}]]
[GROUP BY <nombre campo> [{,<nombre_campo >}]]
[HAVING < condición > [{ AND | OR < condición > }]]
[ORDER BY <nombre campo> | <indice campo> [ASC | DESC]
                 [{,<nombre campo>|<indice campo> [ASC | DESC ]}]]
           Palabra clave que indica que la sentencia de SQL que queremos ejecutar es de
SELECT
           selección.
           Indica que queremos seleccionar todos los valores. Es el valor por defecto y no
ALL
           suele especificarse casi nunca.
DISTINCT Indica que queremos seleccionar sólo los valores distintos.
           Indica la tabla (o tablas) desde la que gueremos recuperar los datos. En el caso
           de que exista más de una tabla se denomina a la consulta "consulta combinada"
FROM
           o "join". En las consultas combinadas es necesario aplicar una condición de
           combinación a través de una cláusula WHERE.
           Especifica una condición que debe cumplirse para que los datos sean devueltos
WHERE
           por la consulta. Admite los operadores lógicos AND y OR.
GROUP
           Especifica la agrupación que se da a los datos. Se usa siempre en combinación
BY
           con funciones agregadas.
           Especifica una condición que debe cumplirse para que los datos sean devueltos
           por la consulta. Su funcionamiento es similar al de WHERE pero aplicado al
HAVING
           conjunto de resultados devueltos por la consulta. Debe aplicarse siempre junto
           a GROUP BY y la condición debe estar referida a los campos contenidos en ella.
```

ORDER

BY

Presenta el resultado ordenado por las columnas indicadas. El orden puede expresarse con ASC (orden ascendente) y DESC (orden descendente). El valor

predeterminado es **ASC.**

JDBC API

Java Database Connectivity, más conocida por sus siglas JDBC, 1 2 es una API que permite la ejecución de operaciones sobre bases de datos desde el lenguaje de programación Java, independientemente del sistema operativo donde se ejecute o de la base de datos a la cual se accede, utilizando el dialecto SQL del modelo de base de datos que se utilice.

El API JDBC se presenta como una colección de interfaces Java y métodos de gestión de manejadores de conexión hacia cada modelo específico de base de datos. Un manejador de conexiones hacia un modelo de base de datos en particular es un conjunto de clases que implementan las interfaces Java y que utilizan los métodos de registro para declarar los tipos de localizadores a base de datos (URL) que pueden manejar. Para utilizar una base de

datos particular, el usuario ejecuta su programa junto con la biblioteca de conexión apropiada al modelo de su base de datos, y accede a ella estableciendo una conexión; para ello provee el localizador a la base de datos y los parámetros de conexión específicos. A partir de allí puede realizar cualquier tipo de tarea con la base de datos a la que tenga permiso: consulta, actualización, creación, modificación y borrado de tablas, ejecución de procedimientos almacenados en la base de datos, etc.

La API de JDBC se conforma de dos paquetes:

- java.sql
- javax.sql

DESARROLLO

Requerimientos:

Hardware:

- Laboratorio de cómputo
- Red computacional
- Proyector

Software:

- Sistema operativo
- Sistema Manejador de Bases de Datos (MySQL, SQL Server, ORACLE, DB2, etc.)
- Java Development Kit (JSDK 7.x)

Instrucciones:

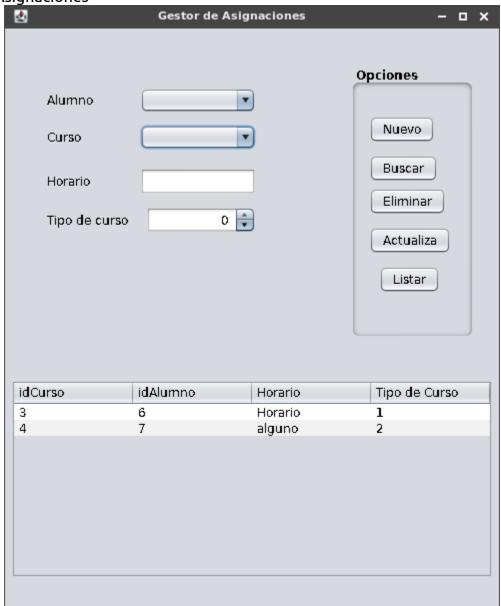

- 1. Cree la siguiente base de datos.
- 2. Crear una interfaz Gráfica en Java Swing para dar soporte a las diferentes actividades de Administracion en cada una de las entidades del punto Anterior, esta interfaz gráfica sera el cliente, que realizará peticiones al Servidor.
- 3. Crear un SocketServidor que permita mantener comunicación con el servidor de bases de datos MySql y permita dar soporte a las operaciones CRUD Basicas para cada una de las Entidades mostradas en la imagen del punto 1.

CONCLUSIONES

La arquitectura cliente servidor es una de las mas antiguas en el área de redes y su eficacia se ha probado por muchos años. La ventaja de implementar este tipo de arquitectura en java es que el lenguaje ya permite mucha facilidad a la hora de escribir el código debido a que ya contiene muchas clases que hacen mas fácil la implementación.

Hacer esta implementación en lenguajes diferentes al estilo C tomaría mucho tiempo y haría que la productividad disminuyera, pues en C se requiere hacer todo a mano, así como estar revisando los mensajes enviados y los mensajes que se reciben.
